# International Plant Nutrition Institute

- IPNI is a not-for-profit, scientific organization
  - established in 2007 from the Potash Phosphate Institute (PPI)
  - Agronomic programs in Africa, China, India, Eastern Europe & Central Asia, Middle East, Oceania, North and South America
- We provide a unified, scientific voice for the world's fertilizer industry; independent, but scientifically credible

*The mission of IPNI is to develop and promote scientific information about the responsible management of plant nutrition for the benefit of the human family*

# World cereal production and fertilizer consumption, million metric tons

# How much crop yield is attributable to fertilization?

## Agronomy Journal

Volume 97

January–February 2005

Number

- Long-term studies: provide invaluable information about crop response to fertilization ...
  - Integrate the effects of year, climate, pest and disease stress, etc.
- Suggest 40 to 60% of crop response is due to commercial fertilizer

### FORUM

#### The Contribution of Commercial Fertilizer Nutrients to Food Production

##### ABSTRACT

Food production systems have come under increased scrutiny in recent years because of the potential for environmental impact from inputs such as N and P. The benefits of nutrient inputs are often minimized in discussions of potential risk. The purpose of this forum is to provide a balanced view of the contribution of commercial fertilizer nutrients to food production. Several long-term studies in the USA, England, and the tropics, as well as a meta-analysis of 12 seasons of crop production were included in the long-term study evaluations. Crops utilized in these studies included corn (*Zea mays* L.), wheat (*Triticum aestivum* L.), and soybean (*Glycine max* L.). The average percentage of yield attributable to fertilizer generally ranged from 30 to 50%. The results of this investigation indicate that the commonly cited generalization that at least 30 to 50% of crop yield is attributable to commercial fertilizer nutrient inputs is a reasonable, if not conservative estimate.

technology and intensified production often involve a greater need for commercial fertilizer nutrients to avoid nutrient depletion and ensure soil quality and crop productivity. The need for increased inputs correctly raises questions about associated risks. Potential risks are of an abundant, affordable, and healthful food supply can be overlooked or understated. To judge any such practice or system, the risks must be evaluated in comparison with the benefits. While misuses of agricultural fertilizers have undoubtedly occurred and concerns about how they are used have sometimes been expressed, it is not to address these issues but to provide evidence of the impact commercial fertilizers have had on agricultural production.

Several attempts have previously been made to estimate how much of the crop production in the USA is attributable to commercial nutrient inputs. These estimates usually range from about 30 to 50% for major grain crops (Nelson, 1990). Determining these estimates presents significant challenges, and assumptions are always required regardless of the approach taken. One difficulty that arises is that crops respond differently to

# P is essential for plant and animal nutrition

- In plants:

- involved in photosynthesis, energy transfer, cell division & enlargement
- root formation and growth
- improves fruit & vegetable quality
- vital to seed formation
- improves water use
- helps hasten maturity

- In animals:

- major component of bones and teeth
- important for lactating animals
- P and calcium are closely associated in animal nutrition
- essential for energy transfer and utilization

# Wheat response to P fertilizer on a P deficient soil in Manitoba

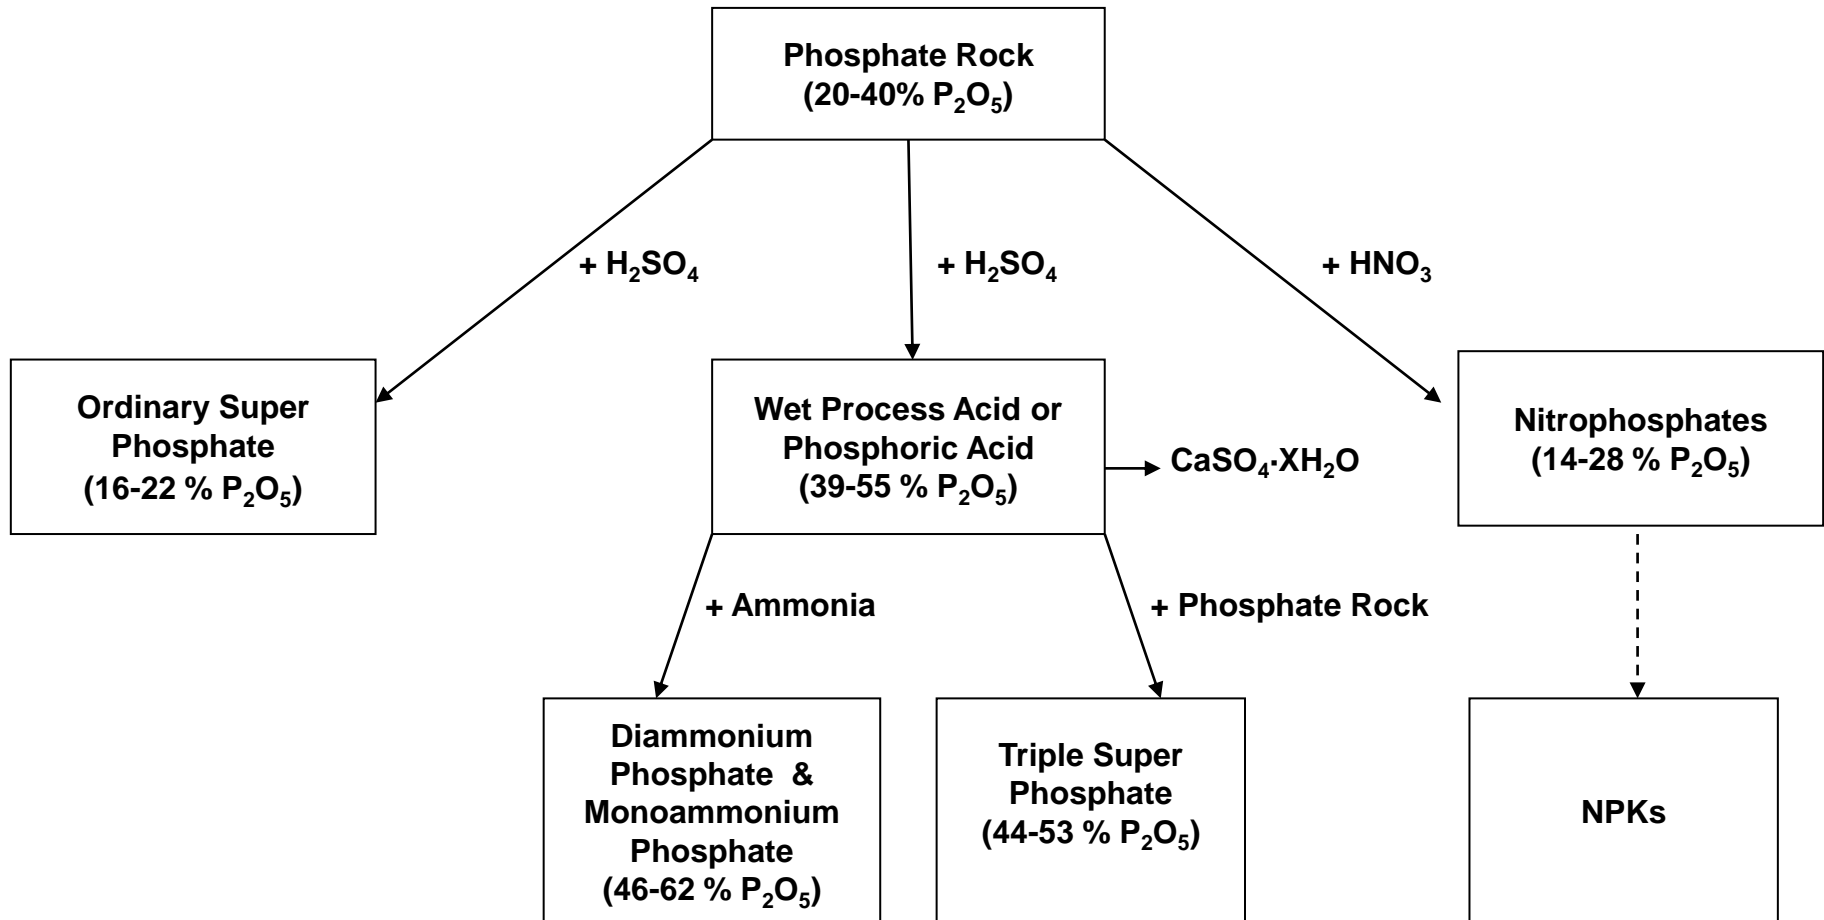

Source: Tomaszewicz, 1992

# Seeds Contain More Phosphorus than Other Plant Parts

Crop	Plant part	Yield level, t/ha	P content, %	P removal, kg/ha
Maize	Grain	9.4	0.22	21
	Stover	8.4	0.17	14
Wheat	Grain	4.0	0.42	17
	Straw	6.1	0.12	7
Rice	Grain	6.7	0.28	19
	Straw	7.8	0.09	7

# Primary raw material for P fertilizer is phosphate rock: $[\text{Ca}_3(\text{PO}_4)_2]_3 \cdot \text{CaF}_2$

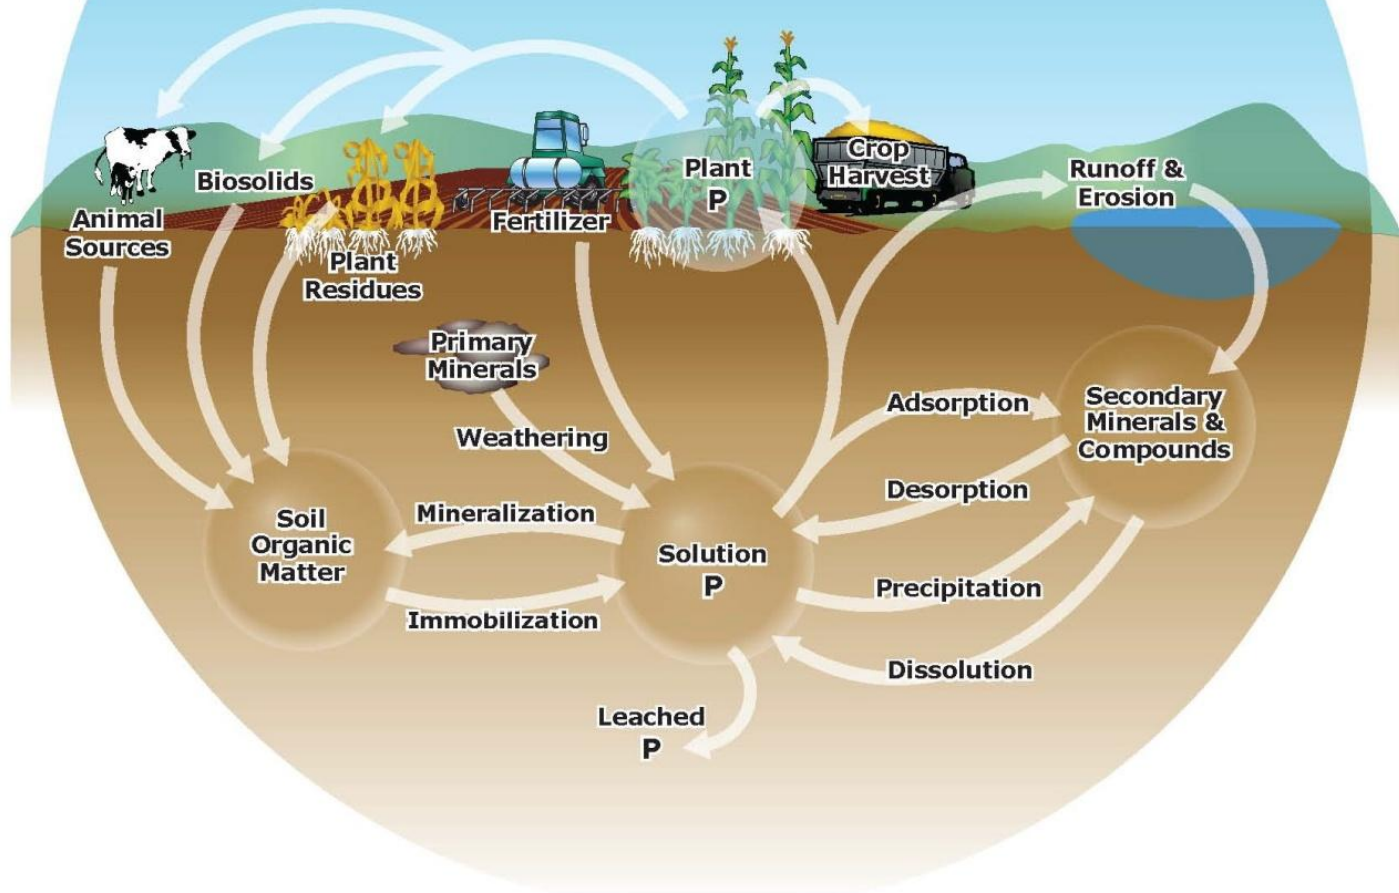

# Phosphorus fertilizer and the soil

- Common commercial P fertilizers are highly ( $\geq 90\%$ ) water soluble
- Once dissolved in soils orthophosphate ions are available for plant uptake
  - primary orthophosphate ion:  $\text{H}_2\text{PO}_4^-$  (pH < 7.0) and secondary orthophosphate ion:  $\text{HPO}_4^{=}$  (pH > 7.0)
- P chemistry in soils is complex — P may become sparingly available to plants in some soils due to formation of reversion products

# The Phosphorus Cycle

# Relative Movement of N, P, K in the Soil

## Nitrogen

Movement in surface soil profile

Nitrogen location 17 days after application

## Phosphorus

Movement in surface soil profile

J. Produc. Agric. 9:1

# P Reduces Residual Soil Nitrate and Potential for Nitrate Leaching

Schlegel, Dhuyvetter, and Havlin, 1996  
J. Produc. Agric. 9:1

# Efficiency of P Fertilizer

- Frequently stated that P is used inefficiently in agriculture
  - percent recovery of P applied in fertilizers usually between 10 and 25%

e.g. Crop fertilized with 25 kg/ha of P removes 18 kg of P from the soil and unfertilized crop removed 15 kg of P from the soil

$$\text{Percent recovery} = \frac{(18 - 15)}{25} \times 100 = 12\%$$

- This method is appropriate for N fertilizers, but of limited use for P. Why?
  - Because N fertilizer has little residual value. Nitrate left in the soil after harvest can be lost by leaching, denitrification, or volatilization
  - Fertilizer P not removed by the crop at harvest remains in the soil
- Low efficiency is an artifact of the method used to calculate it

## Efficiency of soil and fertilizer phosphorus use

Reconciling changing concepts of soil phosphorus behaviour with agronomic information

## Recovery efficiency by balance method for P

- Global review by Syers, Johnston and Curtin (2008).
- When soils are maintained near the critical level for crop yield, P recovery efficiency by the balance method frequently exceeds 90%.

# Nutrient Use efficiency terminology

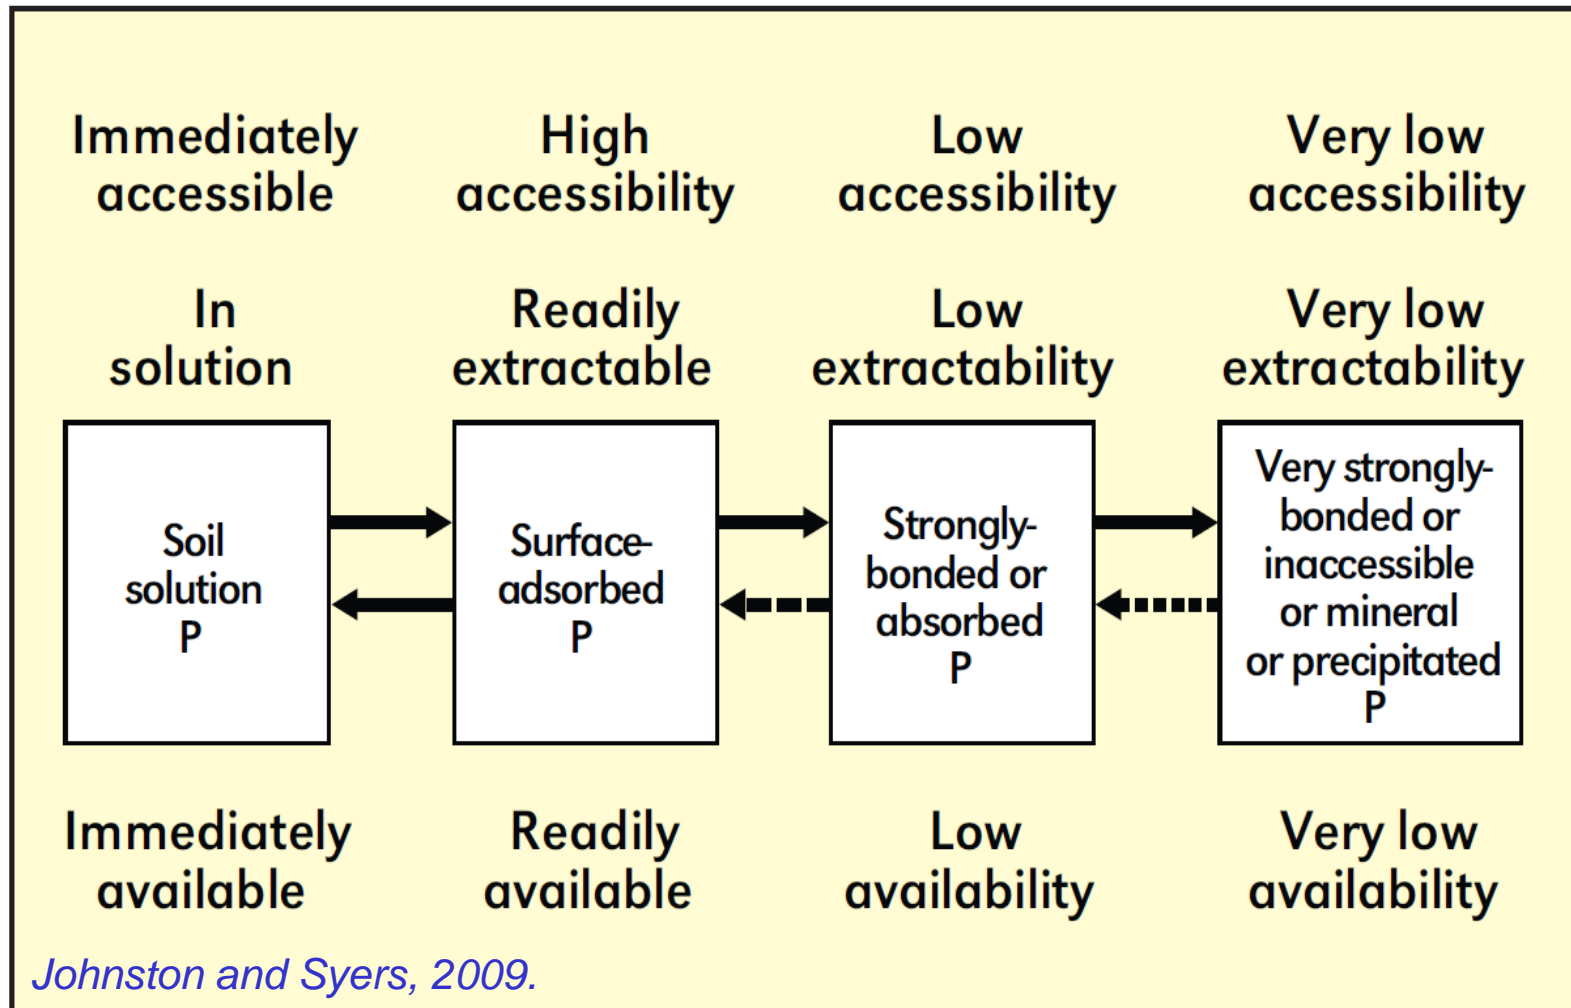

**Example:**

P applied (F)	Grain yield (Y)	P Uptake (U)	P removal ( $U_H$ )
kg/ha	Kg/ha	kg P/ha	kg P/ha
20	$Y = 3,160$	$U = 20$	16
0	$Y_0 = 2,624$	$U_0 = 17$	

NUE Term	Calculation	Example
Agronomic efficiency	$(Y - Y_0)/F$	$(3,160 \text{ kg/ha} - 2,624 \text{ kg/ha}) = 536 \text{ kg grain}$ $536 \text{ kg grain} / 20 \text{ kg applied P} = \mathbf{27 \text{ kg grain/kg P}}$
Recovery efficiency by difference method	$(U - U_0)/F$	$(20 \text{ kg P/ha} - 17 \text{ kg P/ha}) / 20 \text{ kg P applied} = \mathbf{15\%}$
Recovery efficiency by balance*	$U_H/F$	$16 \text{ kg P/ha} / 20 \text{ kg P applied} = \mathbf{80\%}$

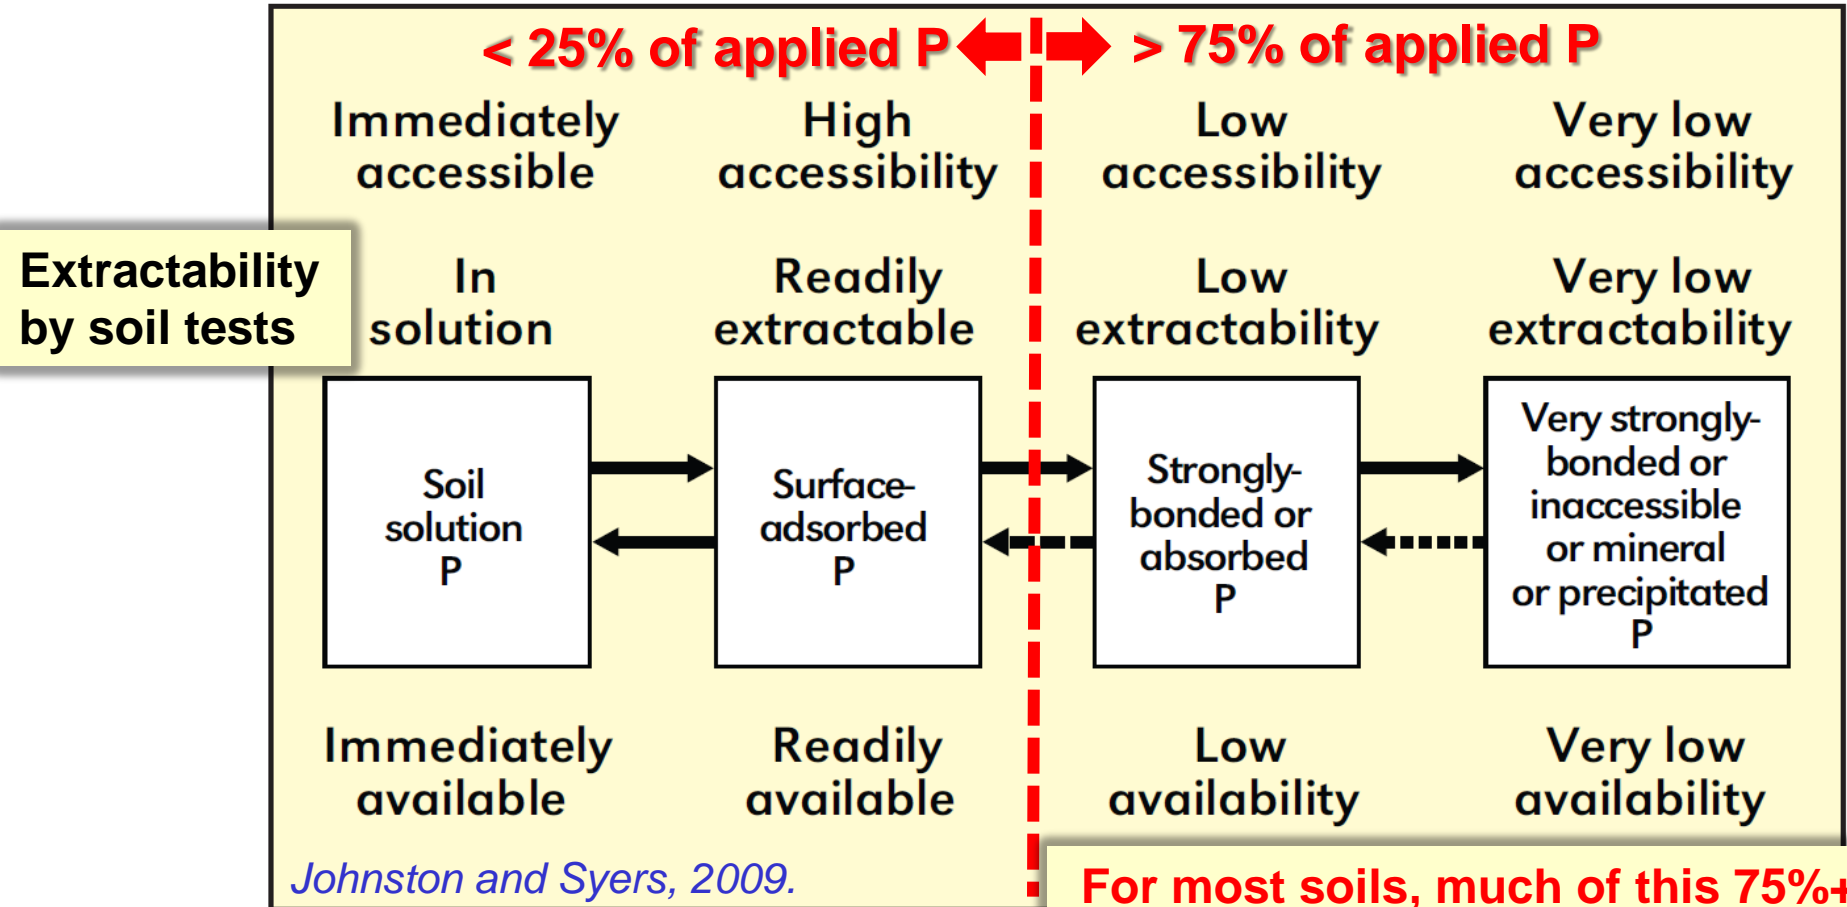

\* Also referred to as “partial nutrient balance” or “removal to use ratio”.

If the percent recovery of P fertilizer in the crop rarely exceeds 20 or 25% ... the remaining P in crop comes from the soil reserves

# Availability and extractability of soil P pools

**For most soils, much of this 75%+ enters the low availability pool ... becomes plant available over time**

Recovery by balance method accounts for fertilizer P that enters the less available pools

P nutrient balance (kg/ha/yr) in corn-based agricultural systems – low input corn in Western Kenya, high input wheat/corn double cropping systems in North China, and corn/soybean rotation in Midwest U.S.

	Western Kenya	North China	Midwest U.S.
P applied as fertilizer	8	92	14
P removed in harvested crop	7	39	23
Balance	+1	+53	-9
Recovery by balance method (removal to use ratio )	0.88	0.42	1.64

Potential yield in these systems were similar, but realized yields were 2 t/ha/yr in Kenya; 8.5 in China, and 8.2 in the U.S. Wheat yielded another 5.8 t/ha/yr in China and soybeans 2.7 t/ha/yr every other year in Illinois.

Illinois Median Bray P in 2005 = 36 ppm, in 2010 = 24 ppm

# Estimated P recovery by balance (removal to use ratio), by hydrologic region, 1987 – 2007

(fertilizer + recoverable manure nutrients + legume N fixation – nutrient removal by crops)

Ratio

{ Crop removal is less than fertilizer use ...  
building soil fertility

Balanced budget (removal = use)

{ Crop removal is greater than fertilizer use ...  
depleting soil fertility

Source: NuGIS, IPNI 2010

# Preliminary soil test P distribution in 2010 compared to 2005 for the Corn Belt 9/2/2010 (12 states plus Ontario)

# 2010 median soil P levels\* and change from 2005 (Soil samples, millions: 2005=2.0; 2010=3.0)

\*Median Bray P1 equivalent, ppm

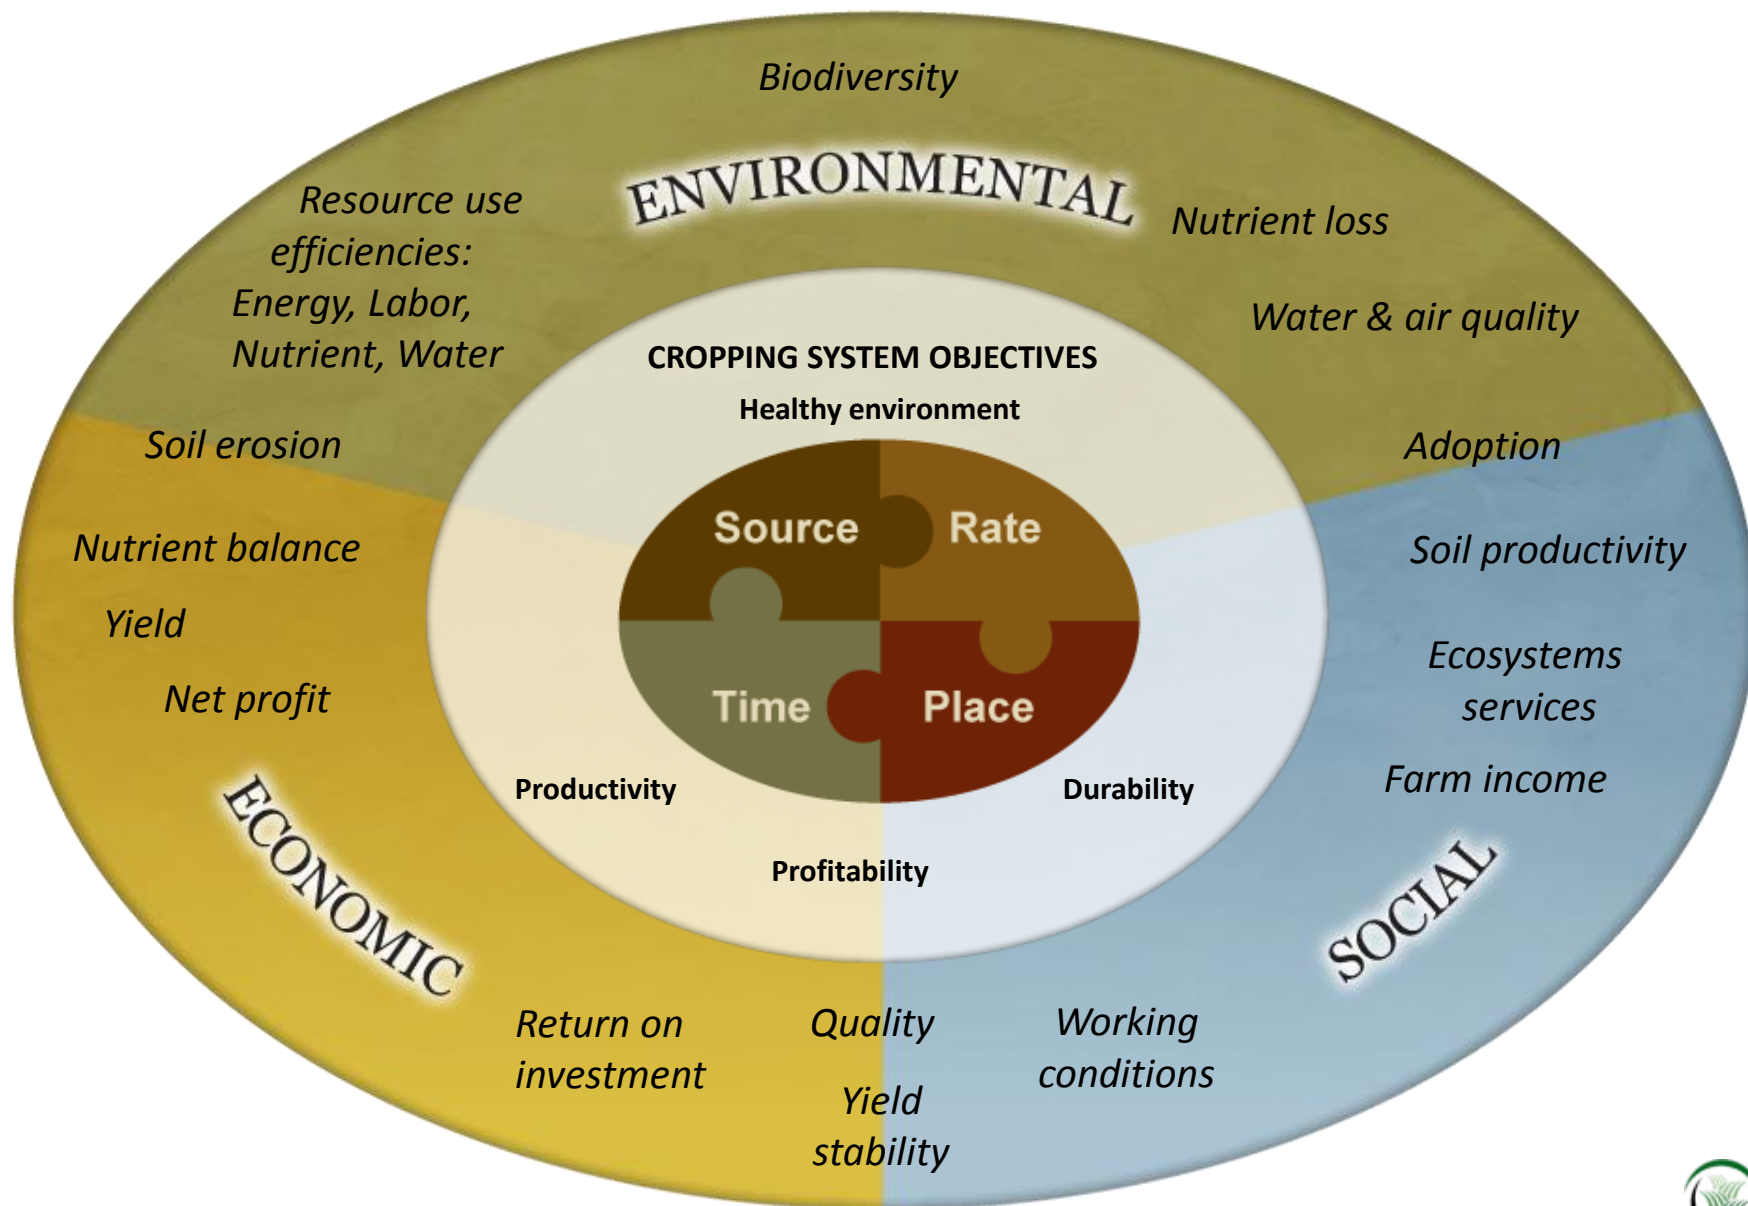

# Phosphorus and the environment

- Eutrophication- the natural aging of lakes or streams by nutrient enrichment
- Nutrient additions can accelerate the process
- P is often the limiting element
- Dissolved oxygen is depleted by excessive plant growth
- BMPs can help minimize P runoff from fields

# Gulf of Mexico Hypoxia Area (new estimates Aug. 2, 2010)

Square miles of hypoxia

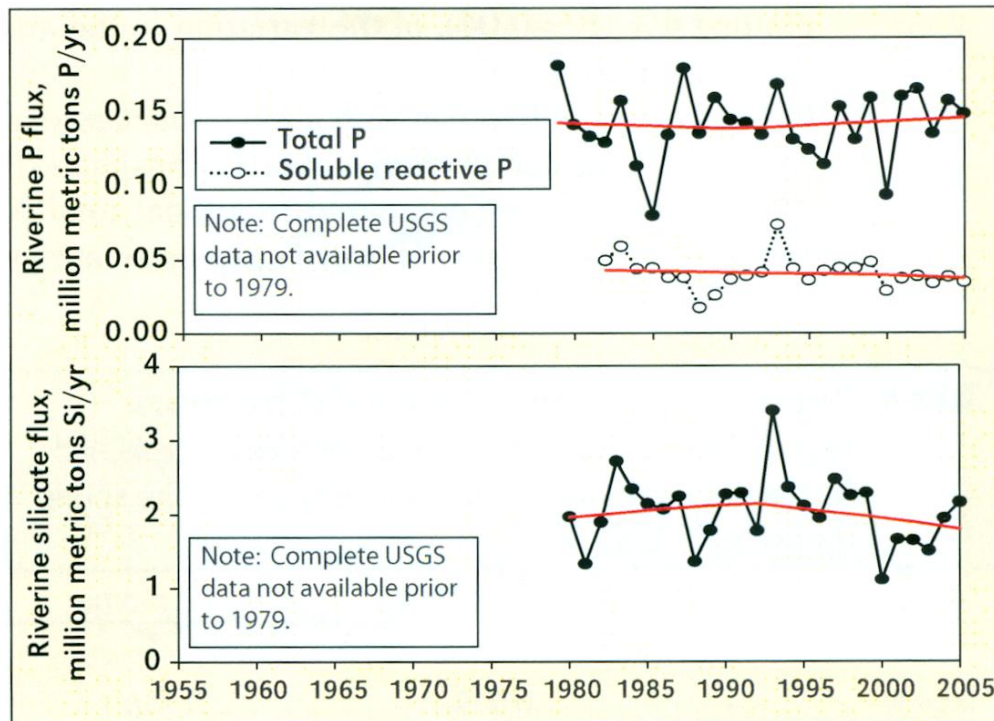

Hypoxia data from N. Rabalais, LUMCON

## Sub-basin Contributions of N & P

**Table 3.** Average annual nutrient yields for the five large sub-basins in the Mississippi-Atchafalaya River Basin for water years 2001-2005. Source: EPA SAB, 2008.

Sub-basin	NO <sub>3</sub> -N	NH <sub>4</sub> -N and organic N (Total Kjeldahl N)	Total P
----- kg/ha/yr -----			
Upper Mississippi	7.1	2.7	0.8
Ohio-Tennessee	6.4	3.3	1.1
Missouri	0.6	0.6	0.2
Arkansas-Red	0.5	0.8	0.1
Lower Mississippi	1.2	-0.5	0.9

# Annual P silicate discharge into Mississippi-Atchafalaya River Basin (MARB) from EPA's SAB on Hypoxia in the northern Gulf of Mexico (2008).

- Total P discharge has remained constant or increased slightly since 1980s
- Orthophosphate P (soluble) has declined slightly

**Figure 4.** Annual P and silicate discharge (flux) for the Mississippi-Atchafalaya River Basin for 1979-2005. Red curves represent statistically-based, smoothed trends.

# Nutrient mass balances estimated for MARB

**Figure 9.** Phosphorus mass balance and net inputs for major regions of the Mississippi-Atchafalaya River Basin through 2005. Source: EPA SAB, 2008.

- Voluntary actions are also reducing the “net” phosphorus (P) balance in the Mississippi River Basin; especially in two key upper sub-basins.
- This is a concern, however, because soil P may be “mined”, and may lead to yield reductions and lower N use efficiency
